

# Data Models for the Cloud

# Relational Model Shortcomings

- Greater Scalability
  - High write throughput / very large datasets
- Independence of few vendors — Move towards Open Source
- Need for different query operations
- Restrictiveness of relational schemas

# Alternatives to Relational Schemes: XML

- Data is often structured hierarchically

```
Invoice = {
  date : "2008-05-24"
  invoiceNumber : 421
}

InvoiceItems : {
  Item : {
    description : "Wool Paddock Shet Ret Double Bound Yellow 4'0"
    quantity : 1
    unitPrice : 105.00
  }
  Item : {
    description : "Wool Race Roller and Breastplate Red Double"
    quantity : 1
    unitPrice : 75.00
  }
  Item : {
    description : "Paddock Jacket Red Size Medium Inc Embroidery"
    quantity : 2
    unitPrice : 67.50
  }
}
```

# Alternatives to Relational Schemes: XML

- Example as a relational scheme
  - `Invoice_Items (invoice.id, description, quantity, unit_price)`
  - `Invoices (date, invoice.id)`

# Alternatives to Relational Schemes: XML

- As an XML document

```
<invoice>
```

```
  <number>421</number>
```

```
  <date>2008-05-24</date>
```

```
  <items>
```

```
    <item>
```

```
      <description>Wool Paddock Shet Ret Double Bound Yellow 4'0" </description>
```

```
      <quantity>1</quantity>
```

```
      <unitPrice>105.00</unitPrice>
```

```
    </item>
```

```
    <item>
```

```
      <description>Wool Race Roller and Breastplate Red Double </description>
```

```
      <quantity>1</quantity>
```

```
      <unitPrice>75.00</unitPrice>
```

```
    </item>
```

```
    <item>
```

```
      <description>Paddock Jacket Red Size Medium Inc Embroidery </description>
```

```
      <quantity>2</quantity>
```

```
      <unitPrice>67.50</unitPrice>
```

```
    </item>
```

```
  </items>
```

```
</invoice>
```

# Alternatives to Relational Schemes: XML

- Advantage of XML
  - Faster to scan
  - Less need for joins
- Disadvantages of XML
  - Each record contains the full or an abbreviated scheme

# Alternatives to Relational Schemes: JSON

- JSON — JavaScript Object Notation
  - Human-readable
  - Organized as key-value pairs

# Alternatives to Relational Schemes: JSON

- JSON record example

```
{
  "firstName": "John",
  "lastName": "Smith",
  "isAlive": true,
  "age": 27,
  "address": {
    "streetAddress": "21 2nd Street",
    "city": "New York",
    "state": "NY",
    "postalCode": "10021-3100"
  },
  "phoneNumbers": [
    {
      "type": "home",
      "number": "212 555-1234"
    },
    {
      "type": "office",
      "number": "646 555-4567"
    },
    {
      "type": "mobile",
      "number": "123 456-7890"
    }
  ],
  "children": [],
  "spouse": null
}
```

# Alternatives to Relational Schemes: JSON

- JSON can use a schema (type definition)
- JSON was first used for data transmission as a data serialization format

# Alternatives to Relational Schemes: JSON

- Many-to-One and Many-to-Many Relationships
  - Modeled by the same value for the same key
    - Problem: Need to standardize / internationalize these values
    - Using id-s instead of plain text to avoid problems
    - Table of id-s reintroduce a relational scheme through a backdoor

# Alternatives to Relational Schemes: JSON

- Résumé
  - Users present people
  - People have jobs, education, and recommenders
- But they share jobs, companies, degrees, schools, recommenders
  - Should they stay text strings or become entities?
    - Latter allows to add information to all resumé
- If recommenders get a photo, then all resumé should be updated with this photo, so better to make recommenders entities

# Alternatives to Relational Schemes: JSON

- Data has a tendency to become less-join free

# Document Databases

- Records are documents
  - Encode in
    - XML
    - YAML
    - JSON
    - BSON (Mongo DB)
  - CRUD operations: create, read, update, delete

# Document Databases

- Enforcing schema
  - Most document databases do not enforce schema
    - —> “Schemaless”
    - In reality: “Schema on Read”
    - RDBMS would then use “Schema on Write”
- Allows schema updates in simple form

# Document Databases

- Schema on Read:
  - Advantages:
    - Data might come from external sources
  - Disadvantages:
    - No data checking

# Document Databases

- Document database support
  - Most commercial database systems now support XML databases

# Query Languages

- Documents lend themselves to object-oriented querying
  - Imperative code
- SQL is declarative:
  - Programmer explains a solution
  - System figures out the best way to find the solution
- Use declarative query languages for document databases

# Query Languages

- Map-Reduce (neither declarative nor imperative):
  - Consists of only two pieces of code
    - Mapping: Selecting from Documents
    - Reducing: Take selection elements and operate on them

# Alternatives to Relational Schemes: Graph Models

- Graphs consists of vertices and edges
  - Example:
    - Social graphs: vertices are people and edges are relationships such “knows”
    - Web graph: vertices are pages and edges are links
    - Road networks: vertices are places and edges are connections

# Alternatives to Relational Schemes: Graph Models

- Relational Database hides semantic relationships

# Alternatives to Relational Schemes: Graph Models

- Document model hides semantic relationships

# Alternatives to Relational Schemes: Graph Models

- Some property values are really references to foreign aggregates
  - Aggregate's identifier is a foreign key
- Relationships between them are not explicitly accessible
  - Joining aggregates becomes expensive

# Alternatives to Relational Schemes: Graph Models

- Relational Database
  - Some queries are simple:

```
SELECT p1.Person
FROM Person p1 JOIN PersonFriend
ON PersonFriend.FriendID = p1.ID JOIN Person p2
ON PersonFriend.PersonID = p2.ID WHERE p2.Person = 'Bob'
```

# Alternatives to Relational Schemes: Graph Models

- Relational Database
  - Some queries others are more involved: Friends of Bob

```
SELECT p1.Person
FROM Person p1 JOIN PersonFriend
  ON PersonFriend.PersonID = p1.ID JOIN Person p2
  ON PersonFriend.FriendID = p2.ID
WHERE p2.Person = 'Bob'
```

# Alternatives to Relational Schemes: Graph Models

- Relational Database

- Some queries others are difficult: Alice's friends of friends

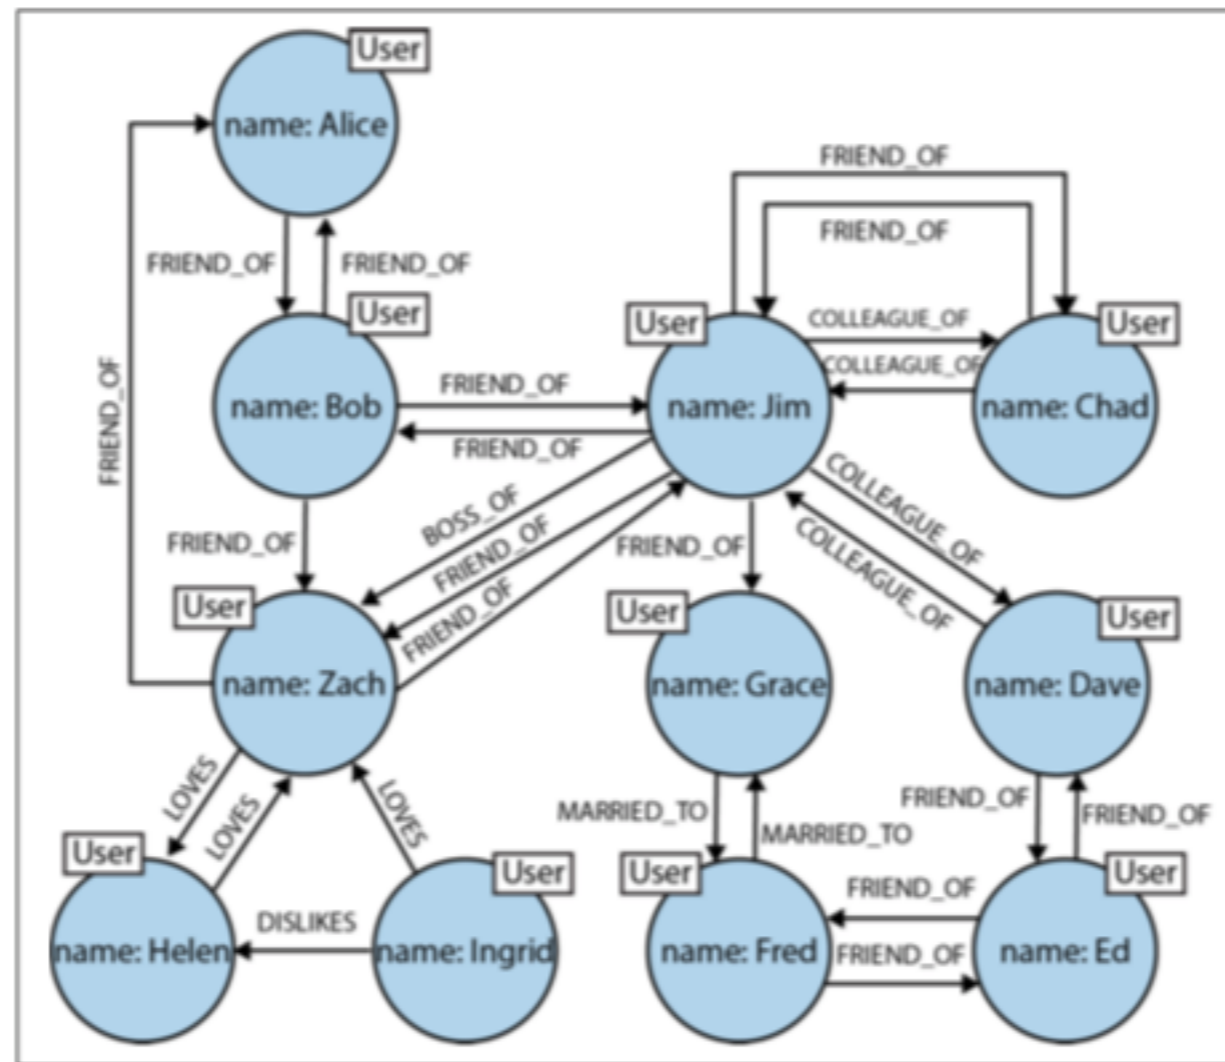

```
SELECT p1.Person AS PERSON, p2.Person AS FRIEND_OF_FRIEND FROM
PersonFriend pf1 JOIN Person p1
ON pf1.PersonID = p1.ID JOIN PersonFriend pf2
ON pf2.PersonID = pf1.FriendID JOIN Person p2
ON pf2.FriendID = p2.ID
WHERE p1.Person = 'Alice' AND pf2.FriendID <> p1.ID
```

# Alternatives to Relational Schemes: Graph Models

- Property graph model by Neon
  - Each vertex consists of
    - A unique identifier
    - A set of outgoing edges
    - A set of incoming edges
    - A collection of properties — key-value pairs
  - Each edge consists of
    - A unique identifier
    - The tail vertex
    - The head vertex
    - A label to describe the relationship
    - A collection of properties — key-value pairs

# Alternatives to Relational Schemes: Graph Models

# Alternatives to Relational Schemes: Graph Models

- Order history as a property graph

# Alternatives to Relational Schemes: Graph Models

- Processing queries in Neo4j
  - Use Cypher (from “The matrix”)
  - Can describe a path

```
(emil) <-[:KNOWS]-(jim)-[:KNOWS]->(ian)-[:KNOWS]->(emil)
```

# Alternatives to Relational Schemes: Graph Models

```
(emil:Person {name:'Emil'})  
  <-[:KNOWS]- (jim:Person {name:'Jim'})  
  -[:KNOWS]-> (ian:Person {name:'Ian'})  
  -[:KNOWS]-> (emil)
```

# Alternatives to Relational Schemes: Graph Models

- Finding the mutual friends of Jim:

```
MATCH (a:Person {name:'Jim'}) -[:KNOWS]->(b) -[:KNOWS]->(c), (a) -[:KNOWS]->(c)
RETURN b, c
```

# Alternatives to Relational Schemes: Graph Models

- Triple Stores
- Information is stored as (subject, predicate, object)
  - Subjects correspond to vertices
  - Objects are
    - A value in a primitive data type — (jim : age : **64**)
    - Another vertex — (jim : friend\_of : thomas)

# Alternatives to Relational Schemes: Graph Models

```
@prefix : </example>
_:lucy a :Person
_:lucy :name "Lucy"
_:lucy :born_in _:idaho
_:idaho a :Location
_:idaho :name "Idaho"
_:idaho :type "State"
_:idaho :within _:usa
```

# Alternatives to Relational Schemes: Graph Models

- Triple stores are the language of the semantic web
- Semantic web:
  - Machine readable description of type of links
    - e.g. image, text, ...
  - Creates web of data — a database of everything
- Stored in Resource Description Framework (RDF)
- SPARQL — query language for triple stores
