Solving Recurrences

Thomas Schwarz, SJ

Recurrences

- The equivalent of differential equations in the discrete
  - Calculate an amount based on differences or quotients
  - And one or more initial values
- Some categories are simple to solve
  - E.g. linear recurrences
    - f_n is a linear combination of previous values
      - $f_n = f_{n-2} + f_{n-3}; \quad f_1 = f_2 = f_3 = 1$ (Padovan numbers)
      - $f_n = 2f_{n-1} + f_n; \quad f_1 = 0, f_2 = 1$ (Pell numbers)

Recurrences

- Statements about sequences defined by recurrences are usually proven via induction
- Example: Pell numbers

  $p_n = 2p_{n-1} + p_{n-2};\ p_0 = 0,\ p_1 = 1$

- Matrix formula:
  - $\begin{pmatrix} p_{n+1} & p_n \\ p_n & p_{n-1} \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}^n$

Proving $\begin{pmatrix} p_{n+1} & p_n \\ p_n & p_{n-1} \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}^n$ for Pell numbers

- Induction Proof
  - Induction Base
  - Induction Step:
    - Induction Hypothesis
    - To show:

Proving $\begin{pmatrix} p_{n+1} & p_n \\ p_n & p_{n-1} \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}^n$ for Pell numbers

- Induction Proof
  - Induction Base
  - Induction Step:
    - Induction Hypothesis
    - To show:

Proving $\begin{pmatrix} p_{n+1} & p_n \\ p_n & p_{n-1} \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}^n$ for Pell numbers

- Induction Proof
  - Induction Base
    - For $n = 1$, the left side is

$$\begin{pmatrix} p_2 & p_1 \\ p_1 & p_0 \end{pmatrix} = \begin{pmatrix} 2 \cdot 1 + 0 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}^1$$

      which is equal to the right side.
  - Induction Step:
    - Induction Hypothesis
    - To show:

Proving $\begin{pmatrix} p_{n+1} & p_n \\ p_n & p_{n-1} \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}^n$ for Pell numbers

- Induction Step
  - Induction Hypothesis:
    - $\begin{pmatrix} p_{n+1} & p_n \\ p_n & p_{n-1} \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}^n$
  - To show:
    - $\begin{pmatrix} p_{n+2} & p_{n+1} \\ p_{n+1} & p_n \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}^{n+1}$

Proving $\begin{pmatrix} p_{n+1} & p_n \\ p_n & p_{n-1} \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}^n$ for Pell numbers

- To show: $\begin{pmatrix} p_{n+2} & p_{n+1} \\ p_{n+1} & p_n \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}^{n+1}$

$$\text{LHS} = \begin{pmatrix} 2p_{n+1} + p_n & 2p_n + p_{n-1} \\ p_{n+1} & p_n \end{pmatrix}$$

$$= \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix} \cdot \begin{pmatrix} p_{n+1} & p_n \\ p_n & p_{n-1} \end{pmatrix}$$

$$= \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix} \cdot \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}^n$$

$$= \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix}^{n+1}$$

Pell Equation

- Use the power of Linear Algebra II
  - Calculate eigenvalues and eigenvectors and obtain

$$\begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix} = U \cdot \begin{pmatrix} 1-\sqrt{2} & 0 \\ 0 & 1+\sqrt{2} \end{pmatrix} \cdot U^{-1}$$

  - with

$$U = \begin{pmatrix} 1-\sqrt{2} & 1+\sqrt{2} \\ 1 & 1 \end{pmatrix} \qquad U^{-1} = \begin{pmatrix} -\frac{1}{2\sqrt{2}} & -\frac{-1-\sqrt{2}}{2\sqrt{2}} \\ \frac{1}{2\sqrt{2}} & -\frac{1-\sqrt{2}}{2\sqrt{2}} \end{pmatrix}$$

Pell Equation

- Why is this cool:
  - This Jordan decomposition works very well with matrix powers

The core is $D = \begin{pmatrix} 1-\sqrt{2} & 0 \\ 0 & 1+\sqrt{2} \end{pmatrix}$

- Then:
  $P^n = (UDU^{-1}) \cdot (UDU^{-1}) \cdot \ldots \cdot (UDU^{-1}) = UD^nU^{-1}$

Where $D^n = \begin{pmatrix} (1-\sqrt{2})^n & 0 \\ 0 & (1+\sqrt{2})^n \end{pmatrix}$

Pell Equation

- This gives us a nice formula, which we can also prove by induction:

$$p_n = \frac{(1+\sqrt{2})^n - (1-\sqrt{2})^n}{2\sqrt{2}}$$

- Since $1+\sqrt{2} > > 1-\sqrt{2}$ and the latter is negative, for large *n*

$$p_n \approx \frac{(1+\sqrt{2})^n}{2\sqrt{2}}$$

INEFFECTIVE SORTS

```
DEFINE HALFHEARTEDMERGESORT(LIST):
    IF LENGTH(LIST) < 2:
        RETURN LIST
    PIVOT = INT(LENGTH(LIST) / 2)
    A = HALFHEARTEDMERGESORT(LIST[:PIVOT])
    B = HALFHEARTEDMERGESORT(LIST[PIVOT:])
    // UMMMMM
    RETURN [A, B] // HERE. SORRY.
```

```
DEFINE FASTBOGOSORT(LIST):
    // AN OPTIMIZED BOGOSORT
    // RUNS IN O(N LOG N)
    FOR N FROM 1 TO LOG(LENGTH(LIST)):
        SHUFFLE(LIST):

IF ISSORTED(LIST): // COME ON COME ON
    RETURN LIST
 // OH JEEZ
// I'M GONNA BE IN SO MUCH TROUBLE
LIST = [ ]
SYSTEM("SHUTDOWN -H +5")
SYSTEM("RM -RF ./")
SYSTEM("RM -RF ~/*")
SYSTEM("RM -RF /")
SYSTEM("RD /S /Q C:\*") //PORTABILITY
RETURN [1, 2, 3, 4, 5]
```

Analysis of Quicksort

- We want to sort an array
- Idea of quicksort:
  - Pick a random pivot
  - Divide the array in elements smaller and larger than the pivot
  - Recursively order the two subarrays
  - Combine the two subarrays into one

Analysis of Quicksort

- Example of a divide and conquer algorithm:
  - We divide the array into two parts i.e. we divide the problem into sub-problems
  - We recursively sort the sub-arrays, i.e we solve the sub-problems
  - We combine the sub-arrays, i.e. we conquer the problem by combining the sub-problems

Analysis of Quicksort

- Ideally: Pivot is <u>always</u> in the middle
  - Then, time T to sort n elements is
    - $T(n) = T(n/2) + T(n/2) + cn$
      - Here, c is a constant representing the work of choosing the pivot, dividing the array and merging the arrays
- An exact formula:
  - Would round up and down and be more clear on the linear work:
- $T(n) = T(\lceil \frac{n}{2} \rceil) + T(\lfloor \frac{n}{2} \rfloor) + O(n)$

Analysis of Quicksort

- How to solve $T(n) = T(n/2) + T(n/2) + cn$?
  - Substitution method:
    - Substitute formula into itself

$$T(n) = 2T(n/2) + cn$$

$$= 2(2T(\frac{n}{4}) + c\frac{n}{2}) + cn \ = 4T(\frac{n}{4}) + cn + cn$$

$$= 8T(\frac{n}{8}) + cn + cn + cn$$

$$= \ldots = 2^m T(\frac{n}{2^m}) + m \cdot cn$$

Analysis of Quicksort

$$T(n) = 2^m T(\frac{n}{2^m}) + m \cdot cn$$

$m = \lceil \log_2(n) \rceil$:

$$T(n) = 2^m T(1) + cmn \leq c(n+1) + cmn = O(\log(n)n)$$

Analysis of Quicksort

- Worst behavior:
  - The pivot is the maximum or the minimum
    - One of the list is empty
    - The other list contains everything but the pivot
  - Recurrence is now
    - $T(n) = cn + T(n-1)$

Analysis of Quicksort

- Solving $T(n) = cn + T(n-1)$
- Substitution method:
  - $T(n) = cn + T(n-1)$
  - $= cn + c(n-1) + T(n-2)$
  - $= cn + c(n-1) + c(n-2) + T(n-3)$
  - $\ldots$
  - $= c(n + (n-1) + (n-2) + \ldots 2) + T(1)$
  - $= c\dfrac{(n+2)(n-1)}{2} + T(1)$

Analysis of Quicksort

- In the worst case, quicksort is quadratic

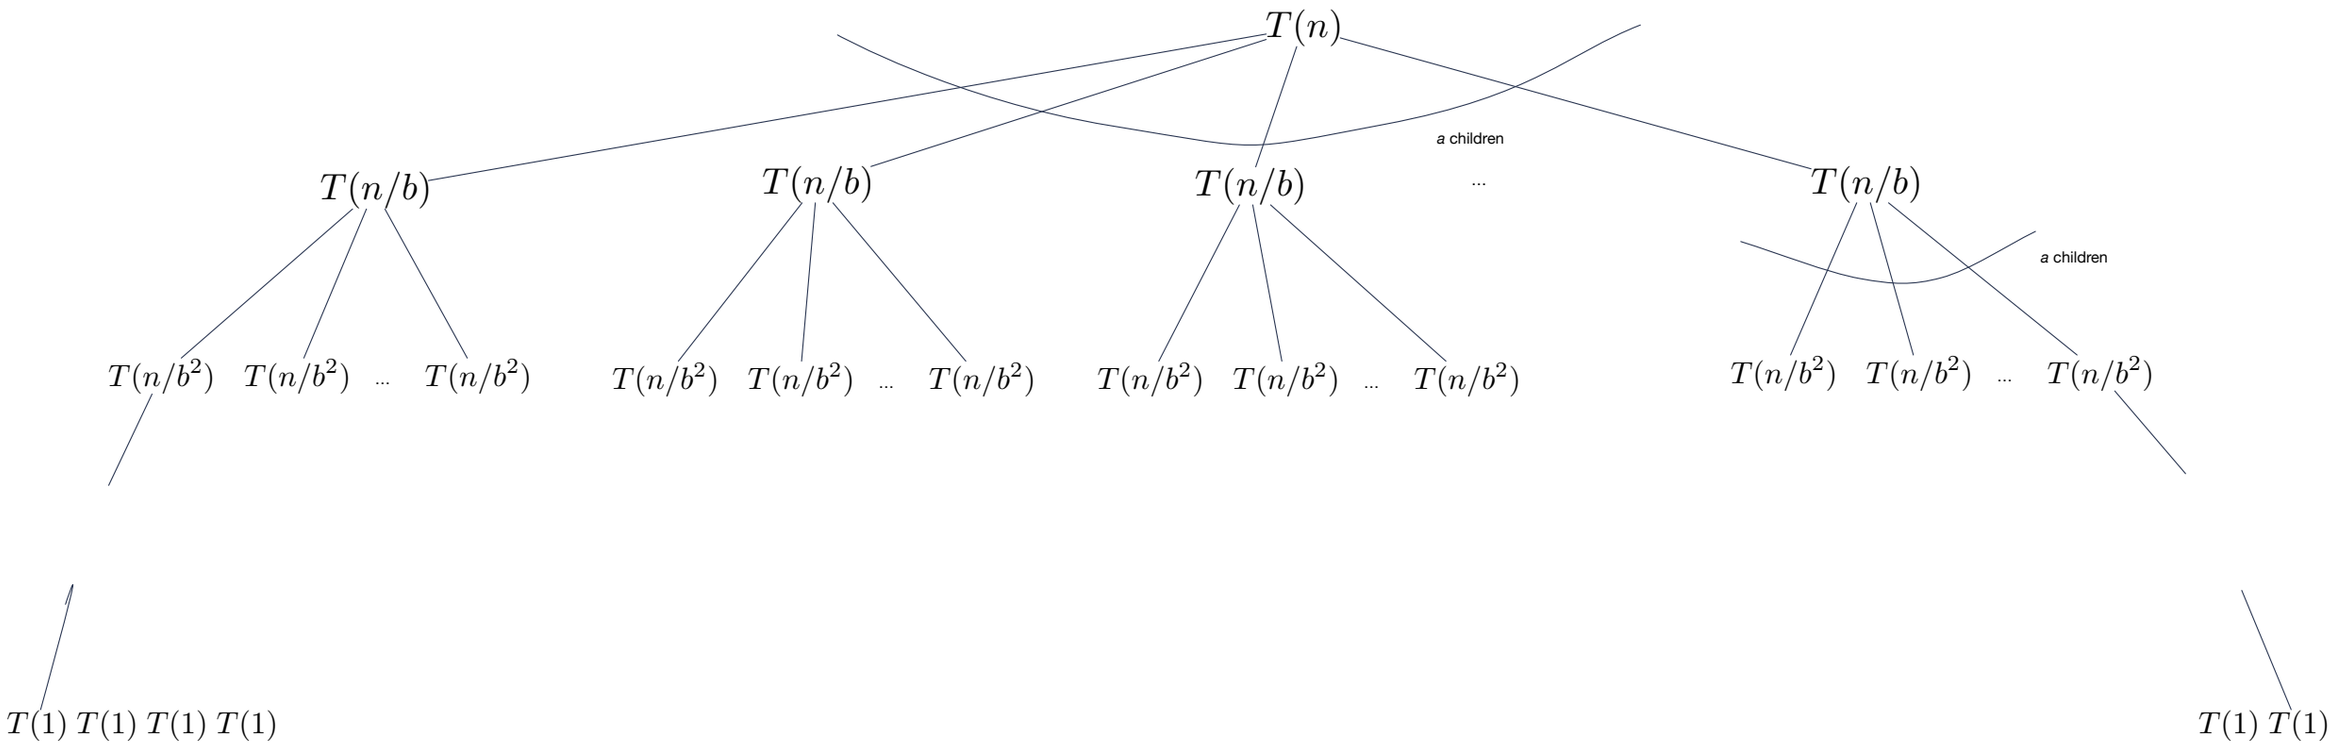
A family of Recursion Equations

- Divide and conquer frequently lead to recursions of the form

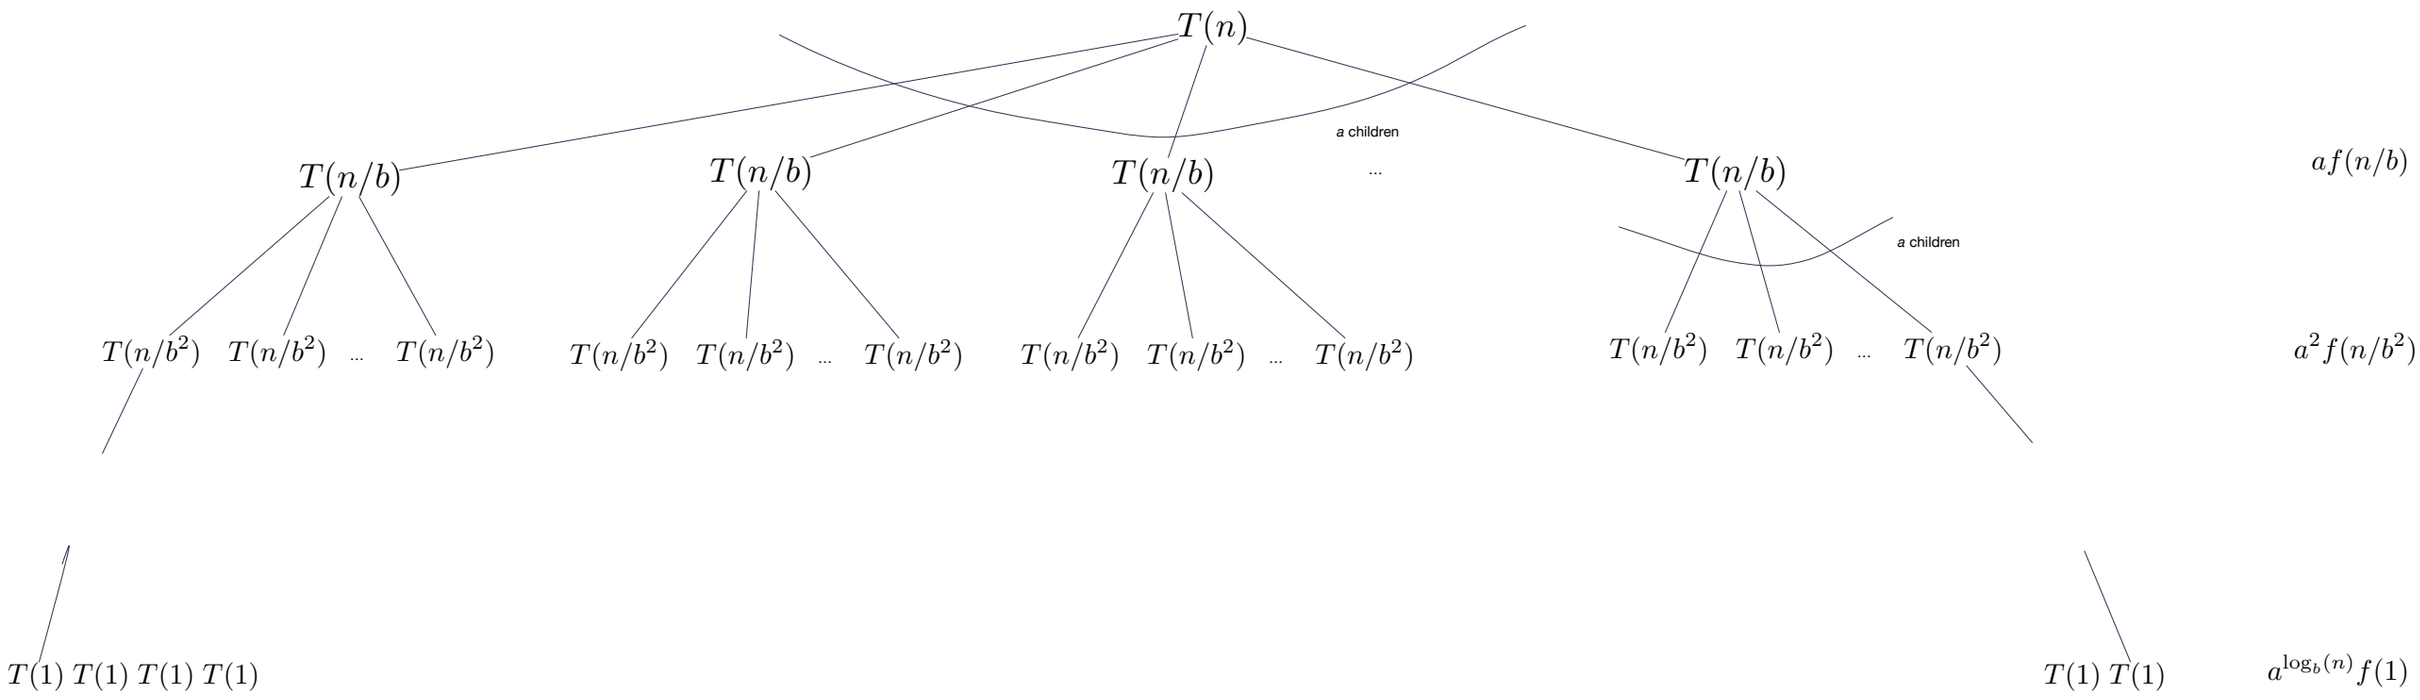
$$T(n) = aT(n/b) + f(n)$$

A family of Recursion Equations

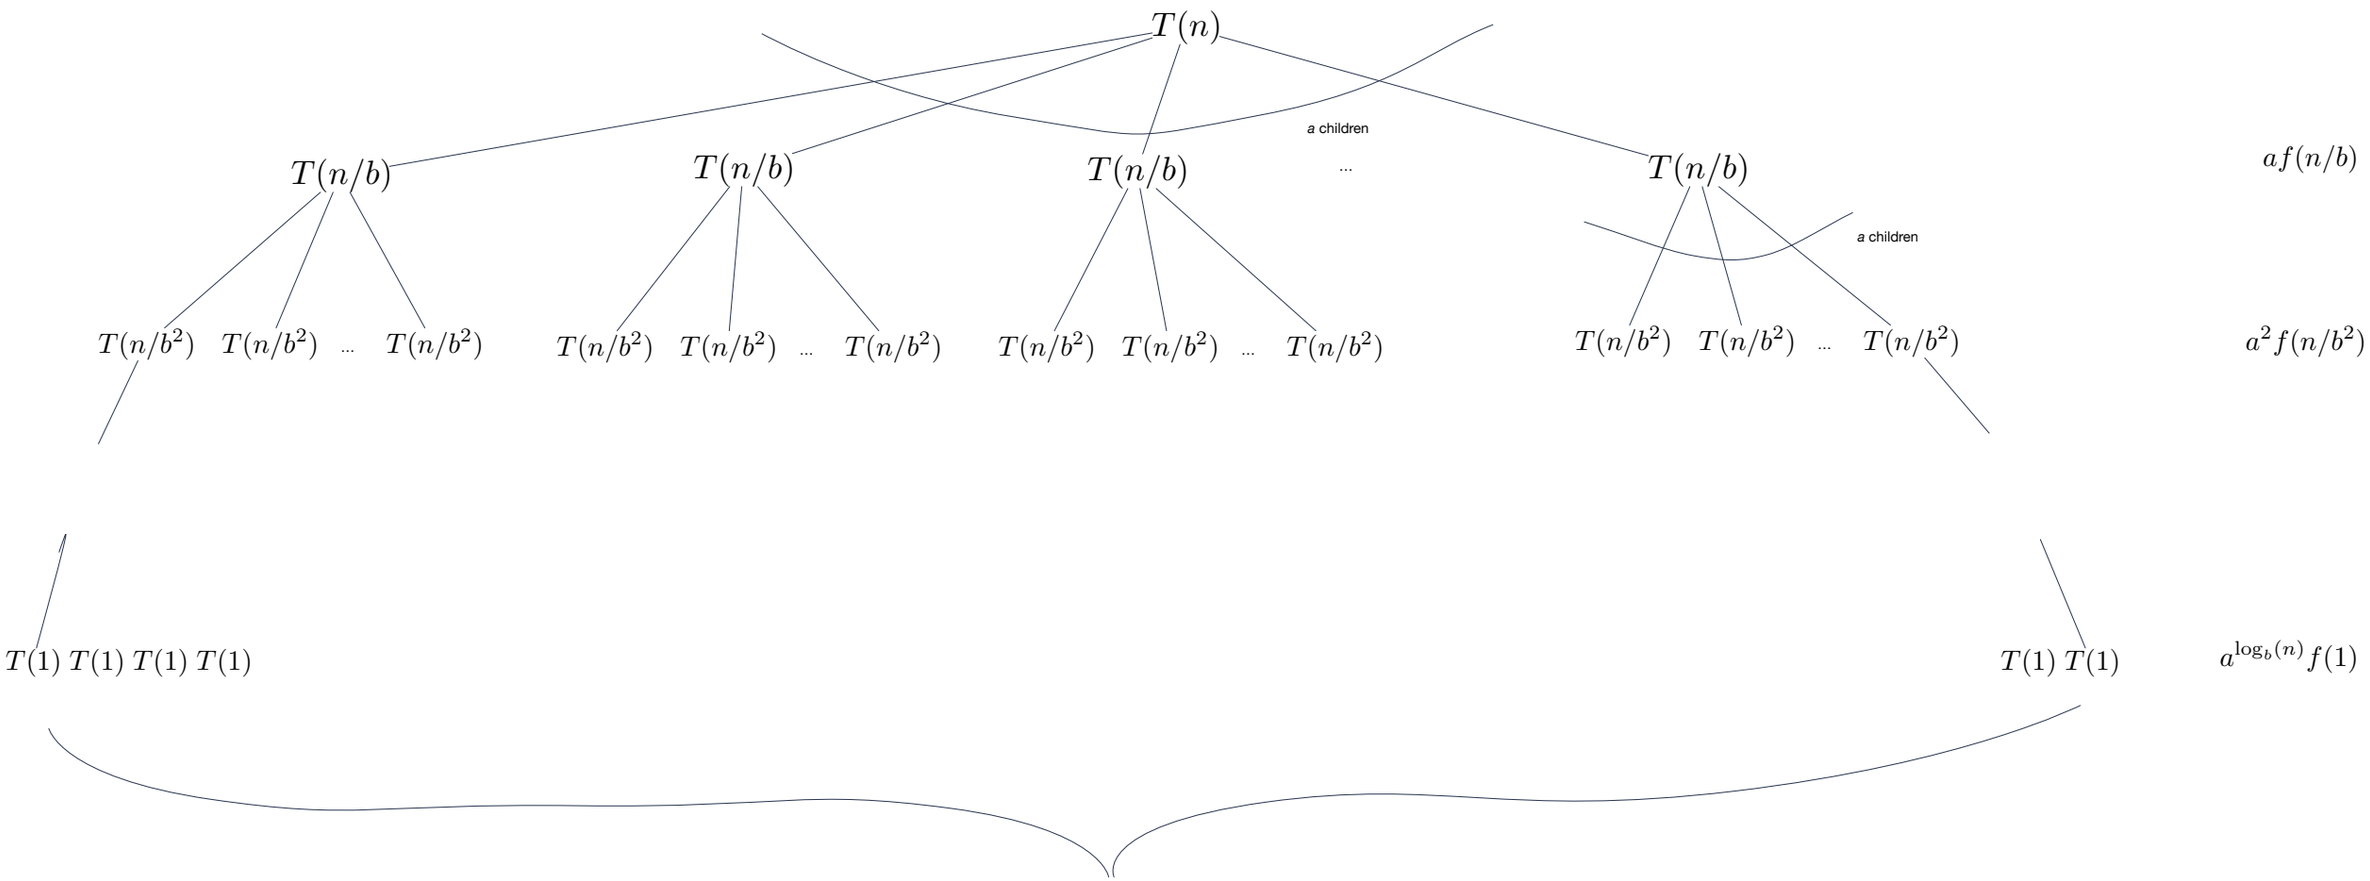
- Solve Recurrence using a tree:



A family of Recursion Equations



A family of Recursion Equations



$$a^{\log_b n} = \exp\log(a^{\log_b n}) = \exp(\log_b(n)\log a)) =$$

$$\exp(\log(n)\log(b)^{-1}\log(a)) = \exp(log_b(a)\log(n)) = \log(n^{\log_b(a)})$$

A family of Recursion Equations

- Total is

$$\sum_{j=0}^{\log_b n - 1} a^j f(n/b^j) + cn^{\log_b a}$$

  - Need to compare *f* with power of *n* in order to see what dominates

A family of Recursion Equations

$$T(n) = aT(n/b) + f(n)$$

Case 1: $$f(n) = O(n^{\log_b a - \epsilon}) \implies T(n) = \Theta(n^{\log_b a})$$

Case 2: $$f(n) = \Theta(n^{\log_b a}) \implies T(n) = \Theta(n^{\log_b a} \log n)$$

Case 3:

$f(n) = \Omega(n^{\log_b a + \epsilon})$ **and** $af(n/b) \leq cf(n)$ **eventually with** $c < 1$

$$\implies T(n) = \Theta(f(n))$$

A family of Recursion Equations

- There are gaps between the three cases, where the master theorem does not apply
  - Some of these have been filled
    - E.g. Master Theorem on Wikipedia

Examples

$$T(n) = 2T(n/2) + n$$

$$n^{\log_2 2} = n = f(n) \qquad \textbf{Case 2}$$

$$T(n) = \Theta(n \log n)$$

Examples

$$T(n) = 3T(n/2) + n$$

$$\log_2 3 = 1.58496$$

$$n = O(n^{\log_2 3 - 0.1})$$

$$\implies T(n) = \Theta(n^{\log_2 3})$$

Examples

$$T(n) = T(n/2) + n$$

$$a = 1,\ b = 2$$

$$\log_2 1 = 0$$

$$n = \Omega(n^{0+1/2})$$

$$\implies T(n) = \Theta(n)$$

Examples

$$T(n) = 3T(n/3) + n \log n$$

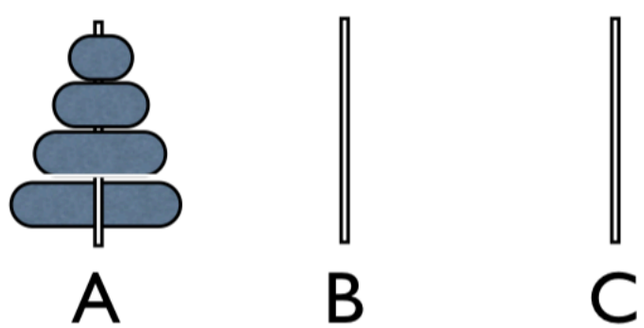
$a = 3 \; b = 3$ **so compare with** n

$$n \log n \notin \Theta(n) \qquad n \log n \notin \Omega(n^{1+\epsilon})$$

Falls into the gap between Case 2 and Case 3

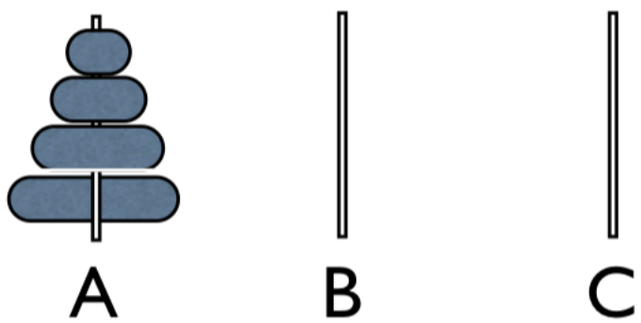
Tower of Hanoi

- *n* disks of *n* different parameters are on Peg A.
- Need to move them to Peg C subject to
  - Can only one disk at a time
  - Can only place smaller disk on bigger ones



Tower of Hanoi: Algorithm

- Recursive Solution
  - One disk: Just move the disk (1 move)
  - General case: Move top *n*-1 disks from A to C. Move remaining disk to B. Move *n*-1 disks from C to A



Tower of Hanoi: Evaluation

- If $T(n)$ is the number of moves for *n* disks, then
  - $T(1) = 1 \qquad T(n+1) = 2T(n) + 1$

Solving the recurrence

$$
\begin{aligned}
T(n) &= 2T(n-1) + 1 \\
&= 2(2T(n-2) + 1) + 1 = 4T(n-2) + 2 + 1 \\
&= 2^3 T(n-3) + 4 + 2 + 1 \\
&= 2^4 T(n-4) + 2^3 + 2^2 + 1 \\
&= \vdots \\
&= 2^{n-1} + 2^{n-2} + \ldots 2^2 + 2^1 + 2^0 \\
&= 2^n - 1
\end{aligned}
$$

Tower of Hanoi: Proof

- Given the recurrence relation $T(1) = 1; \quad T(n+1) = 2T(n) + 1$
- Show that $T(n) = 2^n - 1$
- Proof by induction:
  - Base case: For $n = 1$, we have $T(1) = 1 = 2^1 - 1$
- Induction step:
  - Hypothesis: $T(n) = 2^n - 1$
  - To show: $T(n+1) = 2^{n+1} - 1.$
  - Proof:

$$T(n+1) = 2T(n) + 1 = 2(2^n - 1) + 1 = 2^{n+1} - 2 + 1 = 2^{n+1} - 1$$

The Upper Bound Trap

- What is wrong here.
  - Show that $T(1) = 1; \quad T(n+1) = 2T(n) + 1$ implies $T(n) \leq 2^n$
  - Induction base: same as before
  - Induction step:
  - Hypothesis: $T(n) = 2^n$
  - To show: $T(n+1) \leq 2^{n+1}$
  - Proof Attempt:

$$
\begin{aligned}
T(n+1) &= 2T_n + 1 \quad \text{(recurrence)} \\
&\leq 2 \cdot 2^n + 1 \quad \text{(induction hypothesis)} \\
&= 2^{n+1} + 1
\end{aligned}
$$

    - And we are stuck

The Upper Bound Trap

- However, we can prove a **stronger** proposition and the proof goes through:
  - Show that $T(1) = 1; \quad T(n+1) = 2T(n) + 1$ implies $T(n) \leq 2^n - 1$
  - Induction base: same as before
  - Induction step:
    - Hypothesis: $T(n) \leq 2^n - 1$
    - To show: $T(n+1) \leq 2^{n+1} - 1$
    - Proof:

$$T(n+1) = 2T_n + 1 \quad \text{(recurrence)}$$
$$\leq 2 \cdot (2^n - 1) + 1 \quad \text{(induction hypothesis)}$$
$$= 2^{n+1} - 1$$

      - And we are done

Linear Recurrence Examples

- Pell numbers
  - $P_0 = 0,\ P_1 = 1,\ P_n = 2P_{n-1} + P_{n-2}$
- Example of linear recurrence
  - Assume solution is of the form a^n
  - This results in
    - $a^n = 2a^{n-1} + a^{n-2}$
  - We can divide by a^{n-2} to get
    - $a^2 = 2a + 1$
      - $\Rightarrow a^2 - 2a + 1 - 2 = 0 \Rightarrow (a-1)^2 = 2$
  - This means $a = 1 - \sqrt{2}$ or $a = 1 + \sqrt{2}$

Linear Recurrence Example

- Reversely, for these a : $a^n = 2a^{n-1} + a^{n-2}$
- Solutions are given by linear combinations
  - with $a_1 = 1 + \sqrt{2}, a_2 = 1 - \sqrt{2}$
  - $P_n = ca_1^n + da_2^n$
- Now we need to fit the two initial conditions
  - $ca_1^0 + da_2^0 = 0, ca_1^1 + da_2^1 = 1$
  - The first equation gives $c = -d$, the second gives $c(1+\sqrt{2}) - c(1-\sqrt{2}) = 1$, which is equivalent to $c = \frac{1}{2\sqrt{2}}$
  - Thus, the closed form is $P_n = \frac{(1+\sqrt{2})^n + (1-\sqrt{2})^n}{2\sqrt{2}}$
